Reporting DateTime: 19-Aug-2025 19:53

Serum Bile Acid

Interpretation:

- An elevated fasting level due to impaired hepatic clearance, is a sensitive indicator of liver disease.
- In pregnant women, elevation may serve as a biochemical marker for Obstetric Cholestasis.
- The standard and preferred condition for serum bile acid estimation is the fasting state. The aforementioned reference range corresponds to the fasting state.
- In cases when samples are obtained in the non-fasting state, then following reference ranges apply, based on current clinical guidelines for pregnancy, as bile acid levels may be elevated postprandially:

<19 μmol/L: Gestational pruritus
19–39 μmol/L: Mild intrahepatic cholestasis of pregnancy (ICP)
40–99 μmol/L: Moderate ICP
>99 μmol/L: Severe ICP

- Peak bile acid concentrations are used to assess severity and tend to increase with gestational age.

Methodology: Enzymatic Cycling Colorimetric Technique performed on automated analyzer (Abbott Alinity c).

Note: Change in reference value is effective from 18 June 2025.

Electronically verified report. No signature required. Lab reports should be interpreted by a physician in correlation with clinical and radiologic findings
